

# For what $\underline{Y}_1$ is Variance( $Y_1$ ) maximized?

- The coefficient of the first principal component correspond to the Eigen vector with the maximum Eigen value.

$$\left| \begin{array}{l} \max_{e_1} e_1^T \Sigma e \\ \text{s.t. } e_1^T e_1 = 1 \end{array} \right| \Rightarrow \max_{e_1} \underbrace{e_1^T \Sigma e + \tilde{\lambda} [e_1^T e_1 - 1]}_{F(e_1)}$$

Lagrangian  
multiplier based  
rewrite of  
original constrained  
objective.

$$\nabla_{e_1} F = 0$$

$\Rightarrow$

$$\Sigma e_1 + \tilde{\lambda} e_1 = 0$$

$\Rightarrow e_1$  is an Eigen vector.

$\Rightarrow$

$$\Sigma e_1 = -\tilde{\lambda} e_1 \Rightarrow$$

$$\boxed{\Sigma e_1 = \lambda e_1}$$

$$\max_{e_1} e_1^T \Sigma e_1 \equiv \max_{e_1, \lambda} e_1^T \lambda e_1 = \max_{\lambda} \lambda$$

s.t.  $e_1$  is a Eigen vector.

Choose the  $e_1$  corresponding to  
the largest Eigen value.

## More generally

- The  $i$ -th principal component corresponds the  $i$ -th largest eigen vector.

The variance for the  $i$ th principal component is equal to the  $i$ th eigenvalue.

$$\text{var}(Y_i) = \text{var}(e_{i1}X_1 + e_{i2}X_2 + \dots e_{ip}X_p) = \lambda_i$$

$$\text{cov}(Y_i, Y_j) = 0$$

# The proportion of variance explained

- The total variance of X

- We can show that sum of p Eigen values equals the total variance

$$\sum_{j=1}^p \sigma_{jj}^2 = \sum_{j=1}^p \text{var}(x_j)$$

$$\Sigma = \begin{bmatrix} \sigma_{11}^2 & \sigma_{12} & \dots \\ \sigma_{12} & \sigma_{22}^2 & \dots \\ \vdots & \vdots & \ddots \end{bmatrix}$$

show

$$\sum_{j=1}^p \sigma_{jj}^2 = \sum_{j=1}^p \lambda_j$$

$$\Sigma = \sum_{j=1}^p \lambda_j e_j e_j^T$$

$$e_j^T e_j = 1 = \sum_{r=1}^p e_{jr}^2$$

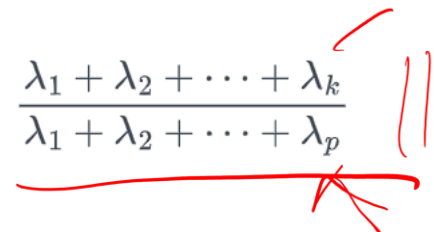

$$\text{Dig} \left\{ \lambda_j \begin{bmatrix} e_{j1} \\ \vdots \\ e_{jp} \end{bmatrix} \begin{bmatrix} e_{j1} & \dots & e_{jp} \end{bmatrix} \right\}$$

$$\text{Trace}(\lambda_j e_j e_j^T) \equiv \lambda_j$$

$$= \lambda_j \begin{bmatrix} e_{j1}^2 \\ \vdots \\ e_{jp}^2 \end{bmatrix}$$

# Reducing number of dimensions

- Variance explained by first k Eigen values

$$\frac{\lambda_1 + \lambda_2 + \cdots + \lambda_k}{\lambda_1 + \lambda_2 + \cdots + \lambda_p}$$

## 11.3 - Example: Places Rated

### Example 11-2: Places Rated

---

We will use the Places Rated Almanac data (Boyer and Savageau) which rates 329 communities according to nine criteria:

1. Climate and Terrain
2. Housing
3. Health Care & Environment
4. Crime
5. Transportation
6. Education
7. The Arts
8. Recreation
9. Economics

[11.3 - Example: Places Rated | STAT 505 \(psu.edu\)](#)

### Notes

---

- The data for many of the variables are strongly skewed to the right.
- The log transformation was used to normalize the data.

# PCA in a nutshell

## 1. correlated hi-d data

("urefu" means "height" in Swahili)

## 2. center the points

## 3. compute covariance matrix

$$\begin{matrix} & h & u \\ h & \begin{pmatrix} 2.0 & 0.8 \end{pmatrix} \\ u & \begin{pmatrix} 0.8 & 0.6 \end{pmatrix} \end{matrix} \rightarrow \text{cov}(h, u) = \frac{1}{n} \sum_{i=1}^n h_i u_i$$

## 4. eigenvectors + eigenvalues

$$\begin{pmatrix} 2.0 & 0.8 \\ 0.8 & 0.6 \end{pmatrix} \begin{bmatrix} e_h \\ e_u \end{bmatrix} = \lambda_e \begin{bmatrix} e_h \\ e_u \end{bmatrix}$$

$$\begin{pmatrix} 2.0 & 0.8 \\ 0.8 & 0.6 \end{pmatrix} \begin{bmatrix} f_h \\ f_u \end{bmatrix} = \lambda_f \begin{bmatrix} f_h \\ f_u \end{bmatrix}$$

`eig(cov(data))`

## 5. pick $m < d$ eigenvectors w. highest eigenvalues

## 7. uncorrelated low-d data

## 6. project data points to those eigenvectors

$$x'_e = x^T e = \sum_{j=1}^d x_{ij} e_j$$

# T-SNE

- Another data projection method, specifically designed for visualizing high dimensional data in two dimensions.
- Preserves local similarities and clusters better than PCA
- Creates non-linear projection
